

ABSTRACT

A substrate for a medical bandaging material is a warp knitted fabric in which the chain stitches are constructed from fiberglass yarns and the inlay stitch is constructed from an inelastic low modulus polymeric yarn, such that fraying and unraveling of a cut edge of the substrate is prevented. The medical bandaging product includes the substrate impregnated or coated with a moisture-curable resin and optionally covered with a tubular hydrophobic wrapping. The bandaging product is stored in a moisture-proof container before use.
